$$H_{\text{Kitaev}} = -\frac{\Delta_{\text{C}}}{2} \sum_{i} \frac{U_{i}}{2} - \frac{\Delta_{\text{f}}}{2} \sum_{\Box} B_{\Box}$$

Localized excitations with finite energy gap Ground-state degeneracy depends on global topology of the lattice. Lattice gauge theory in deconfined regime II Two-fold degenerate ground-state on a cylinder

Local errors are harmless

Creates localized Z_2 fluxes.

Creates local Z_2 charges.

These errors create only virtual states above finite energy gap.

The only dangerous errors are non-local ! They are suppressed by a factor $(noise/\Delta_{c,f})^{L}$

Electric noise transfers one Z_2 flux along v-path and flips P_i : Relaxation in *flux* basis or dephasing in *charge* basis.

Magnetic noise transfers one Z_2 charge along h-path and flips Q_j : Relaxation in *charge* basis or dephasing in *flux* basis.

Basics of Josephson junction arrays

 ϕ_j ; local phase of Cooper pair condensate $\hat{n}_j = \frac{\partial}{i\partial\phi_i}$: number of Cooper pairs on island j $\Delta \phi_j \Delta n_j \simeq 2\pi$ $A_{ij} = \frac{2\pi}{\Phi_0} \int_i^j \vec{A}_{ij} d\vec{r}$ $H = -E_{\mathsf{J}} \sum_{\langle ij \rangle} \cos(\phi_i - \phi_j - A_{ij}) + \frac{E_{\mathsf{C}}}{2} \sum_{ij} (C_{ij}^{-1}) \hat{n}_i \hat{n}_j$ $E_{\rm J}$: Josephson coupling energy $E_{\rm C}$: Charging energy A rhombus with half a flux quantum

Define $\theta_{ij} = \phi_i - \phi_j - A_{ij}$, then:

 $\theta_{12} + \theta_{23} + \theta_{34} + \theta_{41} \equiv \pi, \mod 2\pi$

 \rightarrow Get two-fold degenerate classical ground-state, with $\theta_{ij} = \pm \frac{\pi}{4}$ \rightarrow Quantum fluctuations ($E_{\rm C} \neq 0$) of phases lift this degeneracy

Principle of a protected qubit

$$H = -\frac{\Delta_f}{2} \sum_{i=1}^M \tau_j^z \tau_{j+1}^z$$
$$-\frac{\Delta_c}{2} \sum_{i,j,j'} \sigma_{i,j}^x \sigma_{i,j'}^x$$

Very similar to the Kitaev model:

$$\tau_i^z = \prod_{j=1}^N \sigma_{i,j}^z = P_i$$

Degenerate ground-states of a single chain

$$H_{i} = -\frac{\Delta_{c}}{2} \sum_{j,j'} \sigma_{i,j}^{x} \sigma_{i,j'}^{x}$$

Define $|\pm\rangle_{i,j} = (|\uparrow\rangle_{i,j} \pm |\downarrow\rangle_{i,j}) / \sqrt{2}.$

The two ground-states of H_i are $|+,+,...,+\rangle_i$ and $|-,-,...,-\rangle_i$

$$[H_i, \prod_{j=1}^N \sigma_{i,j}^z] = 0$$

Recall the definition: $\tau_i^z = \prod_{j=1}^N \sigma_{i,j}^z$

$$\begin{aligned} |\tau_i^z = \uparrow\rangle_i &= \left(|+,+,...,+\rangle_i + |-,-,...,-\rangle_i\right)/\sqrt{2} \\ |\tau_i^z = \downarrow\rangle_i &= \left(|+,+,...,+\rangle_i - |-,-,...,-\rangle_i\right)/\sqrt{2} \end{aligned}$$

Ground-states of a single chain(N = 4)

$$\begin{aligned} |\tau_i^z = \uparrow\rangle_i \propto |+, +, +, +\rangle_i + |-, -, -, -\rangle_i & \propto \quad |\uparrow\uparrow\uparrow\uparrow\rangle_i + |\uparrow\uparrow\downarrow\downarrow\rangle_i + |\uparrow\downarrow\uparrow\downarrow\rangle_i + \\ |\uparrow\downarrow\downarrow\uparrow\rangle_i + |\downarrow\uparrow\downarrow\downarrow\rangle_i + |\downarrow\downarrow\downarrow\downarrow\rangle_i + |\downarrow\downarrow\downarrow\downarrow\rangle_i \end{aligned}$$

 $\begin{aligned} |\tau_i^z = \downarrow\rangle_i \propto |+, +, +, +\rangle_i - |-, -, -, -\rangle_i &\propto |\uparrow\uparrow\uparrow\downarrow\rangle_i + |\uparrow\uparrow\downarrow\downarrow\rangle_i + |\uparrow\downarrow\uparrow\uparrow\rangle_i + \\ |\downarrow\uparrow\uparrow\uparrow\rangle_i + |\uparrow\downarrow\downarrow\downarrow\rangle\rangle_i + |\downarrow\downarrow\downarrow\downarrow\rangle_i + \\ |\downarrow\downarrow\uparrow\downarrow\rangle_i + |\downarrow\downarrow\downarrow\downarrow\rangle\rangle_j \end{aligned}$

 τ_i^z is associated to the superconducting phase difference across line *i* of the array, which is twofold degenerate.

Protection of local au_i^z against decoherence

Noise of the form $\sum_{i,j} h_{i,j}^x(t) \sigma_{i,j}^x$ flips τ_i^z , but the stronly coupled M parallel chains correct it efficiently: such error costs an energy of the order E_J/N .

Noise of the form: $\sum_{i,j} h_{i,j}^{z}(t) \sigma_{i,j}^{z}$ commutes with τ_{i}^{z} , or equivalently, induces a term of the form: $|+, +, ..., +\rangle_{i}\langle -, -, ..., -|_{i} + h.c.$

But this decoherence can be made very small !

Assume static and uniform noise $h_{i,j}^{z}(t) = h$

Ground-state doublet splitting $\simeq h^{z} \left(\frac{h^{z}}{\Delta_{c}}\right)^{N-1}$

So, if $h^z/\Delta_c < 1$, spin flip induces only exponentially small dephasing when N is large !

Same conclusion with non-uniform and dynamical noise $h_{i,j}^{z}(t)$, provided $\omega_{noise} \ll \Delta_{c}$

Experimental design

Total phase γ across the array is fixed by the combined effect of the large junction and the flux through the big loop. Qubit encoded in the phase (0 or π) of the central island. Experimental diagnosis of topological protection

$$\begin{split} E_{\text{array}} &= -E_1(\Phi_{\text{Rh}})\cos\gamma - E_2(\Phi_{\text{Rh}})\cos2\gamma\\ \text{If } \Phi_{\text{Rh}} \to \Phi_0(n+1/2), n \text{ integer, then } E_1 \to 0:\\ \Phi_0/2 \text{ periodicity,}\\ \text{else, } E_1 > E_2: \ \Phi_0 \text{ periodicity}\\ \Delta I_{\text{C}} &= \frac{2e}{\hbar}E_1\sin\gamma + \frac{4e}{\hbar}\sin2\gamma \end{split}$$

Manifestation of protection: for $\Phi_{Rh} = \Phi_0(n + 1/2) + \Delta \Phi_{Rh}$,

$$E_1 \simeq E_J \left(\frac{E_J}{\Delta_c}\right)^{N-1} (\Delta \Phi_{\mathsf{Rh}})^N$$

Exponential improvement with system length !

Experimental realization: M. Gershenson et al. (2007)

Measuring the Z_2 charge of the central island

Critical current of the array depends on the Z_2 charge of the central island: Provides a way to measure τ^x

Manipulating the protected qubit

Remarks about conserved quantities in the real physical system

If local magnetic fluxes are exactly $\Phi_0/2$ for each rhombus: local Z_2 charge is conserved, which implies $[Q_i, H_{array}] = 0$.

The array model allows for quantum tunneling processes where Z_2 vortices are created in pairs, which lead to $[P_i, H_{array}] \neq 0$. If we can neglect the processes where a single Z_2 vortex crosses the whole system, we can map the array into an effective Kitaev model where $[P_i, H_{effective}] = 0$.

Effect of noise during the τ^z manipulation

$$\Delta H(t) = f(t) \sum_{i,j} \sigma_{ij}^z + \sum_a \sum_{i,j} \epsilon_{ij}^a(t) \sigma_{ij}^a$$

Effect of various perturbations in qubit space

	Q_j 's conserved	Q_j 's flip
P_i 's conserved	1	$ au^z$
P_i 's flip	$ au^x$	$ au^y$

Noise coupled to σ_{ij}^z

	Q_j 's conserved	Q_j 's flip	
P_i 's conserved	$(f + \epsilon^z)^n 1$	$(f + \epsilon^z)^{N+n} \tau^z$	n even
P_i 's flip	$0 au^x$	$0 au^y$	

Relative effect is of order $\frac{\epsilon^z}{f}$: the angle of the qubit rotation is not very robust.

Noise coupled to σ^x_{ij}

Relative effect on rotation angle is of order $(\frac{\epsilon^x}{\Delta})^2$. Relative size of τ^x term is of order $(\frac{\epsilon^x}{\Delta})^M (\frac{\Delta}{f})^N$. Relative size of τ^y term is of order $(\frac{\epsilon^x}{\Delta})^M$. Noise coupled to σ_{ij}^y

	Q_j 's conserved	Q_j 's flip
P_i 's conserved	$f^p(\epsilon^y)^m 1$	$f^{N-m+p}(\epsilon^y)^m au^z$
P_i 's flip	$f^n(\epsilon^y)^{M+m}\tau^x$	$f^{N-M+p}(\epsilon^y)^{M+m} au^y$

m, p, n-M, even

Relative effect on rotation angle is of order $(\frac{\epsilon^x}{f})^2$. Relative size of τ^x term is of order $(\frac{\epsilon^x}{f})^N$ (if M = N). Relative size of τ^y term is of order $(\frac{\epsilon^x}{f})^N$ (if M = N). Remarks about the au^x manipulation

$$\Delta H(t) = g(t) \sum_{i,j} \sigma_{ij}^{z} + \sum_{a} \sum_{i,j} \epsilon_{ij}^{a}(t) \sigma_{ij}^{a}$$

Formally similar to the τ^z manipulation !

Summary: effect of noise during qubit manipulation

Angle of rotation is no longer robust: the strength of the manipulation term should be larger than the noise which acts in the same channel.

Provided this condition is satisfied, there is still some form of protection for the direction of the rotation applied in qubit space, in the sense that a larger size helps.

Open questions on the effect of noise during qubit manipulation

i)Putting back the true array Hamiltonian, for which strictly speaking, $[P_i, H_{array}] \neq 0$. As we have seen, these terms are associated to processes of the form:

which lift the degeneracy of the central island, whose phase tunnels between 0 and π , thus selecting its Z_2 charge as the good quantum number of the qubit.

ii)Include explicitely dynamical noise during manipulation

Computational issues I: hierarchical approximation

Series composition of Z_2 junctions

 $V(\phi) = -E_2 \cos(2\phi)$

Parallel composition

Computational issues II: single rhombus as Z_2 junction

Conclusions

1) Kitaev's Z_2 lattice model implemented in the low energy sector of some Josephson junction arrays.

2) These arrays are composed of fully frustrated rhombi.

3) Topological protection arises in the phase where quantum phase fluctuations destroy the 2e condensate, while preserving the 4e condensate.

4) Experimental evidence for this phase: observation of enhanced immunity against static flux fluctuations, evidence of a finite Δ_c . 5) Some form of protection is still expected to hold during qubit manipulation.
